    left: -999rem;
  }
}
/* this displays the menus as drop downs */
ul li:hover ul { left: auto; }
}
```

Icons

Start File

The first thing we need to do is copy the icons from the assets folder to images in our start folder.

Open the index file in your browser and notice that the navigation is at the bottom of the page below the footer. We want persistent navigation stuck to the bottom of the screen. To make this happen we need 4 lines of code.

Please open the small-nav file.

Add position: fixed and then bottom 0.

These two will keep the nav at the bottom of the screen regardless page scrolling.

Now add width 100% and give it a background color of \$primaryColor from the variables.

Notice that the blue blends a bit with the page blue

Lets add border-top: that is a solid 1px line at 50% black

Now its easier to separate the nav from the page.

Now lets take the four main menu items and display them horizontally using float left and a width of 25 percent.

Now you can sort of see the 4 blocks of text. Its a bit of a mess but creativity has never been clean endeavor.

Now lets style the anchors using display block which we always use with anchors as links. This allows us to use a height of 50px and a width of 100%. Now the 100% is the full width of the list item which we already set as 25% of the page width. This does not make a big change yet but these are essential before we through in the graphics.

In order to display the background image properly, we need four statements. First we display one of the icons using background-image and a url to the deals.png file. This is what it look like.

Lets tell the image to display only one time using no-repeat.

We will center the icon in the anchor both horizontally and vertically

We will reduce the size using auto for the width and 36px for the height. Using auto maintains the correct image proportion.

Now when we look at it the deals icon looks good in all four main menus anchors. Now lets change the icon for the remaining buttons.

If you look at the code, three of the four statements are true for all the icons and only the background image statement needs to change.

Lets come down here and using an li with nth child of 1 lets talk to the first menu item. We will remove the background image statement from up here and move it down here.

Now the deals icon only appear on the first main icon. It also shows up on the sub menus but we will take care of that later.

Copy this line and paste it three more times. Change the child to 2, 3 and 4. Change the icons to destination, resort and cruise.

Now the icons are all showing up properly in the 4 main menu items.

Open the index and notice that I have a span tag around the text for each main menu anchor

In the small nav file let's hide the text using display none.
Now we only see the icons.

Let's work on the sub menu items using ul li ul
We already set the height of the top level icons to 50px up here so let's position the sub menu items as absolute and set the bottom at 50 so they are just above the other links.
Now you can see them above the others.
We should set their x-index to 99 to ensure they are above anything else on the page
We will move them so they line up at the left edge of the screen.
While we're at it we will set the background color to 50% black so we can see them a little better.

Now we can see both sub menu items stacked together above the main links.
You can now see that the sub menu items are also taking 25% of the page width so let's remove the float and set the width to 100%.

Now we're ready to style the anchors.

create a new selector for the primary ul li submenu ul li a

Please set the background color of the anchor to \$menuColor and the text color to white.
Now we can see some real progress.

Lets remove the background image and remove the text decoration underline.

Notice that these sub menu items are following the parent height of 50px so lets change that to height of auto.

Now they are all smashed at the bottom.

Lets add some padding to increase the size of the button to make them clickable and separate them using margin of .5rem at the top and bottom and 0 at the sides.

At this point you could be done with the sub links if you liked that look. However, let me show you something else just in case you want to try it.

Set the margin right and left to 5%

This means that we need to reduce the width to 90%

Now let round the edges using 5px

Finally add a box shadow of 0 right 2px down 1px blur and 50% rgba black.

This provides another option in case you like it better.

What we are seeing is both sets of sub menu items exactly on top of each other. Now its time to show them only on touch.

Please create a new rule for `ul li:hover ul`.

This kicks in to play when the user touches on mobile screens or hovers with a mouse

Remember that earlier in the `ul li ul` we had to set the bottom to 50px to see the sub menu items.

Lets remove that statement and move it to the hover rule we just created. Now when we refresh and click, our sub menu items appear on touch.

Lets change Chrome to responsive and make a couple more changes. Notice that on mouse hover there is no color change.

Lets add a `ul li hover a` color of menu color.

This way the active menu item matches the sub menu items color. notice that the sub menu items do not respond to mouse hover.

Lets add another rule to darken the sub menu item color using sass `darken` by 10%, I am not sure how many people will shrink their browser and view the page but just in case, we are prepared to impress them.

Now if you will change your emulated device to a medium screen you can see that I have to scale the page to 50% to see the bottom and that is too small to see clearly what we are doing. Therefore I am going to be using the responsive option and set the width to about 560px wide which is within the medium screen range. Now I can use 125% scale and you can see the icon at the bottom of the screen better.

For the medium screen I want to add the text below the icons and reduce the icon size.

Lets start by talking to the span inside the anchor and change the display to block. The result is creating the two selectors we will need for medium navigation.

First add `ul li a` and then `ul li a span`.

Lets show the text using `display block`.

The text is showing but it's too large and the wrong color.

Lets remove the default underline, change the color to white and set the font size smaller

We now have descriptive text but it's in the wrong place.

Lets change the position of the anchors to `relative` which will then allow us to change the position of the child element to `absolute`. Now we can move the text to the bottom of each anchor at 5px above the bottom.

That's exactly what I was looking for.

Now we need to center the text within each anchor.

lets set the width of each span to full width and then we can center the text

The text looks great, Now all we need to do is shrink the icons

In the small nav the icons were auto and 36px.

In the medium nav lets use auto and 26px. We will position the icons in the center horizontally and down 5px from the top to match the 5px used for the text.

Now those are some pretty great looking icons.

The large screen links are a standard horizontal list with dropdown on hiver. We have been doing these for the last several units so I provided the code for you in the snippets file. Copy everything from snippets and paste it in large below the body selector.

Because the html position of the links is at the bottom of the page. we need to force the nav to the top using position absolute and top 0. Everything else here should be familiar.

Change your page size to 100% and wider than 1028 and you will see the navigation links appearing.

Lets turn off the inspect tools and look at the site from small... to medium... to large.

Now pat your self on the back and upload this to a real server for testing.
